# CYTOMORPHOLOGY OF SOME GRASSES (POACEAE) FROM LAHAUL-SPITI (HIMACHAL PRADESH), INDIA 

Raghbir C. Gupta ${ }^{1}$; Harbans Singh Chauhan ${ }^{2}$; M.I.S.Saggoo ${ }^{3}$; Navjot Kaur ${ }^{4 *}$<br>${ }^{1,3,4}$ Department of Botany Punjabi University Patiala-147002, India<br>${ }^{2}$ Govt. College for girls, Patiala-147001, India<br>E-mail: navjot21mono@rediffmail.com

#### Abstract

Meiotic study and pollen fertility was investigated in thirty five grass species belonging to twenty three genera from different localities of Lahaul-Spiti. This is the first cytological study in the grasses from this alpine Himalayas. Bromus gracillimus ( $\mathrm{n}=7$ ) and Melica persica $(\mathrm{n}=10)$, are cytologically worked out for the first time from world, whereas Calamogrostis pseudophragmites ( $\mathrm{n}=7$ ), Helictotrichon pretense ( $\mathrm{n}=7$ ), Poa lahulensis $(\mathrm{n}=14)$, Stipa jacquemontii $(\mathrm{n}=21,22)$, S. koelzii $(\mathrm{n}=11)$, S. splendens $(\mathrm{n}=22)$, Paspalum distichum $(\mathrm{n}=28)$ and P. longifolium $(\mathrm{n}=30)$ show the varied chromosome reports at the world level.

Key Words: Cytomorphology, Grasses (Poaceae), Lahaul-Spiti, meiosis.

## INTRODUCTION

LLahaul and Spiti are the two remote Himalayan valleys of Himachal Pradesh (India) lying on the Indo-Tibet border. It covers an area of $13,835 \mathrm{sq}$. kms. Lahaul-Spiti district can be divided into two main parts i.e. Lahaul valley and Spiti valley. Lahaul valley is situated towards the West whereas Spiti valley lies in the middle of Ladakh and Tibet, and on the Eastern side of the district with Kaza as its head-quarter. It is a mountaneous state and its altitude varies from $3000-4,500 \mathrm{~m}$. Due to harsh climatic conditions, the area is dominated with prostrate, thick, hairy and bushy type of vegetation. From the cold deserts of Lahaul-Spiti region, Aswal and Mehrotra (1994) reported 985 species of 353 genera belonging to 79 families of Dicots, Monocots and Gymnosperms. The district is inhabited by 'Swangla' and 'Gaddi' tribal communities. Due to difficult terain, the LahaulSpiti area had not attracted the attention of many
cytogeneticists, except for recent reports from the department. As there is hardly any cytological work on grasses from the area, so the present exploration was done. The family Poaceae is one of the largest family with maximum economic importance. The family has documented evidence for the exploitation of most of the cytogenetical phenomena such as polyploidy, aneuploidy, apomixis with lot of cytological diversity. There are many studies on the cytology of the family from South Indian, Plains of North India and temperate Himalayas, but absolutely no report of chromosomal study from Lahaul-Spiti area.

## MATERIALS AND METHODS

For the collection of materials, cytological survey of grasses had been carried out from the valleys of Lahaul-Spiti area. Young inflorescences were collected and fixed in Carnoy's fixative (Alcohol: Chloroform: Acetic
acid in 6:3:1) for 24 hours and were transferred to $70 \%$ alcohol for preservation at $4^{\circ} \mathrm{C}$. Meiotic studies were carried out by preparing smears of pollen mother cells (PMCs) in $1 \%$ acetocarmine. Photomicrographs of chromosome counts were made from freshly prepared slides using Leica Qwin and Nikon 80i Eclipse Microscope. Pollen fertility was estimated by their stainability in $1 \%$ glycerol-acetocarmine. Well stained pollen grains were considered as fertile and shriveled or unstained nuclei as sterile. Voucher specimens were submitted to Herbarium, Department of Botany, Punjabi University, Patiala (PUN).

## RESULTS AND DISCUSSION

Presently, thirty five wildly growing grass species, falling under eleven tribes, belonging to twenty three genera from different localities of Lahaul-Spiti (H.P.) are cytomorphologically investigated. The information on name of the species, locality with altitude, accession number, chromosome number, ploidy level, habit and pollen fertility are presented in Table 1.

## TRIBE: BRACHYPODIEAE

## Brachypodium sylvaticum P. Beauv.

It shows the regular meiosis with $\mathrm{n}=9$ at diakinesis and A-I (Figs. 1, 2). The chromosome number is in confirmation with the earlier reports from India and outside India (Mehra 1982).

Elymus semicostatus (Nees ex. Steud) Melderis Cytologically, all the populations of the species show the chromosome count of $\mathrm{n}=14$ with normal meiotic course (Fig. 3), and relatively low pollen fertility. The present meiotic course is in conformity with the previous reports by Mehra and Sharma $(1972,1977)$ from Gulmarg (Srinagar) and Ranikhet (Nainital).

## TRIBE: BROMEAE

## Bromus gracillimus Bunge

Cytological study of the species reveals the diploid chromosome count with $\mathrm{n}=7$ at M-I (Fig. 4), which is the first chromosome report for the Indian population and confirms the previous
reports from Russia (Podlech and Diaterle 1969). It shows normal meiosis with high pollen fertility.

## B. tectorum L.

Extensive cytological studies on 7 populations from the high altitudinal range of Lahaul-Spiti area revealed the same chromosome number of $\mathrm{n}=7$ at diakinesis (Fig. 5). All the populations show normal meiotic behavior with high pollen fertility ( $84-99 \%$ ). The present report is in line with the previous report by Sharma and Sharma (1979).

## B. unioloides Kunth.

Cytologically, the meiotic course reveals the presence of $\mathrm{n}=7$ (Fig. 6) with normal meiosis and almost cent per cent pollen fertility. The present report of diploid cytotype confirms the previous reports by Sharma and Sharma (1979).

## TRIBE: POEAE

Agrostis pilosula Trin.
The haxaploid ( $2 \mathrm{n}=42$ ) chromosomal count has been confirmed with the presence of 21 bivalents at diakinesis. The species also shows interchromosomal connections at A-I (10-12\% PMCs) and chromosomal bridges at A-I/T-I (11$13 \% \mathrm{PMCs}$ ) (Figs. 7-9) which leads to abnormal microsporogenesis, heterogenous sized pollen grains and low pollen fertility (62-78\%). Mehra and Sharma (1975) recorded the same chromosome number from Tiffin Top, Nainital ( 2100 m ) and Toong-Soong Darjeeling ( 1800 m ). Calamogrostis pseudophragmites (A. Haller) Koeler

Meiotic study on the single population from high altitudes of Spiti area showed 7 bivalents at early M-I. The further course of meiosis was abnormal with the presence of interbivalent connections at M-I ( $14 \%$ ), late disjunction of bivalents at A-I (11.32\%) (Figs. 10-12), although the pollen fertility was high (86.6\%). The present chromosome report is a first ever diploid ( $\mathrm{n}=7$ ) cytotype for the species. Previously, tetraploid ( $\mathrm{n}=14$ ) cytotype was reported from Kashmir Himalayas (Koul and Gohil 1991).

*species with abnormal meiotic course

## Dactylis glomerata L.

Four populations of the species were studied from the Lahaul-Spiti area with diploid chromosome count $(\mathrm{n}=7$ ). Besides this, the species shows irregular meiosis in the form of chromatin transfer ( $29 \%$ PMCs) and chromatin bridges at A-I/T-I/A-II/T-II (17.3\% PMCs) (Figs. 13-15), which subsequently resulted in heterogenous sized pollen grains and low pollen fertility ( $68 \%$ ). The present chromosome count confirms the previous reports (Koul and Gohil 1990).

## Festuca rubra L.

The species studied cytologically from the high altitudinal regions of Spiti area showed the presence of $n=14$ at M-I (Fig. 16), with subsequent normal meiotic course. The same chromosome number has been reported by

Mehra and Remanandan (1973) from Pehalgam area of Srinagar.

Helictotrichon pretense (L.) Pilg.
The species is found to be diploid with $\mathrm{n}=7$ at diakinesis ( $\mathrm{n}=7$ ) (Fig. 17). The chromosomes are relatively large in size and meiotic course is normal with cent per cent pollen fertility. Cytologically, the species is first time worked out for an Indian accession and gives a new chromosome report at world level as earlier the species has been reported with $\mathrm{n}=21,56$ and 63 (Hubbard 1954; Lovkist and Hultgard 1999 and Röser 1997).

Koeleria macrantha (Ladeb.) Schult.
The species is collected from the bank of flowing water in Lahaul area. Meiotic studies on the species reveal the presence of $7: 7$

## Plate-I

chromosomes at A-I with normal course of meiosis and high pollen fertility (Fig. 18). The present report is in conformity with the previous reports of Mehra and Sharma (1975).

## Poa alpina L.

The species is distinguished from the other species with ovate to pyramidal inflorescence tinged with purple. Meiotic study of the species shows the presence of $\mathrm{n}=14$ at diakinesis with normal course of meiosis (Fig. 19).

The present report is in conformity with the previous reports of Ghorai and Sharma (1981).

## P. aппиа L .

Cytological investigation of the species reveals the presence of 14 bivalents $(n=14)$ at diakinesis (Fig. 20). Meiosis is found to be normal. The present chromosome count is in conformity with the previous reports (Sharma and Khosla 1989).

[^0]The identifying key point of the species is that the leaf blades are abruptly contracted to a hooded tip often tinged with purple. Cytological investigation reveals the presence of $\mathrm{n}=14$ (Fig. 21), and is in conformity with the previous report given by Koul and Gohil (1987).

## P. lahulensis L.

Cytological investigation reveals the presence of 14 bivalents ( $\mathrm{n}=14$ ) (Fig. 22). Cytologically, worked out for the first time from world, with normal meiotic course but has low pollen fertility ( $68.8 \%$ ).

## P. pretense L.

Meiotically, the species is normal which showed 14 bivalents ( $\mathrm{n}=14$ ) at diakinesis (Fig. 23). The present report confirms the previous reports by Ghorai and Sharma (1981) from India, and Tischler (1934) from outside India.
Trisetum spicatum (L.) K. Richt.
Meiotic study showed the presence of 14 bivalents ( $\mathrm{n}=14$ ) at M-I (Fig. 24). The present report confirms the previous reports from North India (Mehra 1982).

## TRIBE: PHLEAE

Alopecurus arundinaceous Poir.
Cytologically, the species shows the presence of 14 bivalents ( $\mathrm{n}=14$ ) at M-I (Fig. 25). Meiosis is found to be normal. The present chromosome count is in conformity with the previous reports (Mehra and Sunder 1970).

## Phleum alpinum L.

The species shows great morphological variations. Two populations (P1 and P2) collected from the Lahaul-Spiti area are found to be diploid $(\mathrm{n}=7)$ and tetraploid $(\mathrm{n}=14)$, respectively (Figs. 26-28). Besides a little morphological disparity, the tetraploid cytotype shows abnormal meiotic course with the presence of chromatin bridges observed at A-I/T-I ( $9-11 \%$ PMCs), which results in heterogenous sized fertile and sterile pollen grains and reduced pollen fertility ( $66 \%$ ). Population (P1) is normal with high pollen fertility. Both the cytotypes are common and are reported earlier from different parts of India

Pashuk (1987) reported diploid cytotype, whereas Mehra and Remanandan (1973) reported tetraploid cytotype from India and outside India (Probatova and Sokolovskaya 1980). Petrova and Stoyanova (1998) reported B- chromosomes in the diploid cytotype.

## TRIBE: MELICEAE

Melica persica Kunth.
The species shows morphological distinction between two cytotypes. Two populations were worked out, population P1 shows $\mathrm{n}=9$ where as P2 with $\mathrm{n}=10$ chromosome number (Figs. 29, 30). The population with $\mathrm{n}=10$ is a new varied chromosome report from the world and the pollen fertility is slightly reduced (78.6\%). The cytotype ( $\mathrm{n}=9$ ) confirms the previous reports from North India (Mehra and Sharma 1972; Gohil and Koul 1986).

## TRIBE: STIPEAE

Oryzopsis lateralis (Regel) Stapf.
Meiotically, the species revealed the presence of 12 bivalents ( $\mathrm{n}=12$ ) at M-I (Fig. 31), which is in conformity with the previous reports from India (Mehra and Sharma 1975, 1977).

Stipa jacquemontii Jaub. \& Spach.
During the present study, three populations were worked out from the different localities of Lahaul-Spiti. Two populations (P1 and P2) showed $\mathrm{n}=21$ chromosome count. Meiotic analysis showed some sort of spindle abnormality that was reflected in the form of unequal distribution in chromosomes. Some of the PMCs shows scattered chromosomes at A-II (6-7\% PMCs), few PMCs with chromatin bridges at T-II (7.6\% PMCs) (Figs. 32-34), which leads to the abnormal microsporogenesis which (4-5\% PMCs) lead to the formation of polyads, besides tetrads and heterogenous sized pollen grains. Further, it leads to reduced pollen fertility. The population (P3) reveals 22 bivalents ( $\mathrm{n}=22$ ) (Fig. 35). It shows normal meiotic behavior. Both the cytotypes are the new chromosome reports for the species, as the only earlier report is of $2 \mathrm{n}=24$ (Mehra and Sharma 1975). Both the cytotypes show great morphological variations.

S. koelzii R. R. Stewart

Meiotic study on the species showed the presence of 11 bivalents ( $\mathrm{n}=11$ ) at M-I (Fig. 36). Meiotic course is normal. The present chromosome report for the species is a new chromosome report from world.

## S. splendens Trin.

Meiotic study on the species exhibited the normal meiotic behavior with the presence of 22 bivalents ( $\mathrm{n}=22$ ) (Fig. 37). The presently reported chromosome count is a new varied chromosome report from world, as the earlier reported chromosome numbers are $\mathrm{n}=23$ from Srinagar (Gohil and Koul 1986) and n=24 from outside India (Love 1948).

## TRIBE: ARUNDINEAE

## Arundo donax L.

Cytollogically, the species shows the presence of 16 bivalents ( $\mathrm{n}=16$ ) at M-I (Fig. 38) showing normal meiotic behavior and high pollen fertility. The present chromosome count is in conformity with the previous reports from India (Mehra 1982, Sinha et al. 1990). Larsen (1963); Devesa et al. (1991); Delay (1947) and Gorenflot et al. (1972) reported $n=30,5055$ and 56 , respectively, from outside India.
Neyraudia arundinacea (L.) Henrard
Cytologically, the species revealed the presence of 20 bivalents at M-I. The meiotic behavior is observed to be abnormal with the presence of high frequency of laggards (33\%) at A-I,II/T-I,II (Figs. 39-41), subsequently affecting microsporogenesis as micronuclei in tetrads and heterogenous sized pollen grains. The present chromosome number has been reported earlier from India (Mehra and Kalia 1976) as well as outside India (Larsen 1963) with low pollen fertility.

## TRIBE: CYNODONTEAE

Muhlenbergia himalayensis Hack. ex Hook. f.
The cytological investigation of the species reveals the presence of 20 bivalents ( $\mathrm{n}=20$ ) at diakinesis (Fig. 42). This chromosome number is stable in the species as the same number is earlier reported from India (Mehra and Sharma 1972) and outside India (Teppner 2002).

Sporobolus coromondelianus (Retz.) Kunth

During the present studies, the material was collected from high altitudinal regions of Himachal Pradesh (Lahaul-Spiti). The meiotic couse is normal with the presence of 18 bivalents at M-I (Fig. 43). This confirms the various earlier reports from India (Bir et al. 1987, 1988) and outside India (Moinuddin et al. 1994).

## S. diander (Retz.) P. Beauv.

Meiotic study on the species revealed the presence of 18 bivalents at M-I (Fig. 44). The meiotic course is normal which confirms the previous report from India (Bir and Sahni 1985).

## S. tremulus (Willd.) Kunth

Meiotic studies on the species reveal the presence of 12 bivalents at M-I (Fig. 45) with low pollen fertility and normal meiotic course. The species is first time worked out cytologically from the world.

## TRIBE: PANICEAE

## Paspalum distichum L.

Cytological investigation on the species reveals the presence of 28 bivalents at M-I (Fig. 46), that is first ever octaploid cytotype for the species. Previously, $\mathrm{n}=10,15,20$ and 24 are reported (Mehra 1982; Chatterjee 1975; Bir and Singh 1983).

## P. longifolium Roxb.

Meioic analysis of the species collected from the high altitudes revealed the presence of 30 bivalents ( $\mathrm{n}=30$ ) at M-I (Fig. 47). The species shows the new cytological report for the species from world. The previous reports of $\mathrm{n}=20$ and 25 were reported from India (Mehra 1982; Malik and Mary 1970), whereas, $\mathrm{n}=20$ and 40 were reported from outside India.

Pennisetum flaccidum Griseb. ex Roscheb.
The present meiotic analysis reveals the chromosome count of $\mathrm{n}=9$ at M-I (Fig. 48). This is in conformity with the previous reports from India (Koul and Gohil 1987, 1991).

## TRIBE: ANDROPOGONEAE

Chrysopogon gryllus subsp. Echinulatus (Nees ex Steud.) Cope

During the meiotic analysis the species is found to be diploid with 10 bivalents at M-I (Fig. 49). Present study confirms the previous report by Sinha et al. (1990). Mehra (1982) reported 2B chromosomes in the diploid cytotype.

Lasiurus hirsutus (Forssk.) Boiss.
Meiotic study on the species revealed the presence 9 bivalents which are equally distributed at A-I (Figs. 50, 51). The presently reported chromosome count is in conformity with the previous reports from India (Bir and Sahni 1986) and outside India (Faruqi et al. 1979).

## CONCLUSION

Presently, five species show new euploidy levels as were not reported earlier:Octaploidy in Paspalum distichum ( $2 \mathrm{n}=8 \mathrm{x}=56$ ), hexaploidy in P. longifolium ( $2 \mathrm{n}=6 \mathrm{x}=60$ ), tetraploidy in Poa lahulensis ( $2 \mathrm{n}=4 \mathrm{x}=28$ ) and in case of Stipa jacquemontii both tetraploidy ( $2 \mathrm{n}=4 \mathrm{x}=44$ ) and triploidy ( $2 \mathrm{n}=3 \mathrm{x}=42$ ). Among the 35 species studied from the Lahaul-Spiti area19 species ( $54.2 \%$ ) show various levels of polyploidy in comparison to diploid level ( $45.7 \%$ ). Thus, it concludes and reveals that in case of grasses polyploidy is more frequent than diploids.

## ACKNOWLEDGEMENT

The authors are thankful to UGC (SAP-III grant) and DBT (IPLS grant) for financial assistance and also thankful to UGC for awarding teacher fellowship (Harbans singh).
